5

6 **Abstract.**

7 This article investigated whether the atmospheric temperature had any role in the
8 spread and vulnerability to COVID-19 worldwide and how that knowledge can be
9 utilized to contain the fast-spreading disease. It highlighted that temperature was an
10 important factor in transmitting the virus, and a moderately cool environment was the
11 most favourable state for its susceptibility. In fact, the risk from the virus is reduced
12 significantly in high temperature environment. Warm countries and places were likely
13 to be less vulnerable. We identified various degrees of vulnerability based on
14 temperature and specified countries for March and April. The maximum reported
15 case, as well as death, was noted when the temperature was in the range of around
16 275°K (2°C) to 290°K (17°C). Countries like the USA, UK, Italy and Spain belonged
17 to this category. The vulnerability was moderate when the temperature was less than
18 around 275°K (2°C) and countries in that category were Russia, parts of Canada and
19 few Scandinavian countries. For temperature 300°K (27°C) and above, a significantly
20 lesser degree of vulnerability was noted. Countries from SAARC, South East Asia,
21 the African continent and Australia fell in that category. In fact, when the temperature
22 was more than 305°K (32°C), there was a unusually low number of reported cases
23 and deaths, (till April, global maximum temperature reached upto 310°K (37°C)). For
24 warm countries, further analyses on the degree of vulnerability were conducted for
25 the group of countries from SAARC and South East Asia and individual countries

26 were compared. We also showed countries can switch from one vulnerability state to
27 another based on the variability of temperature. We provided maps of temperature to
28 identify countries of different vulnerability states in different months of the year.

29 That influence of temperature on the virus and previous results of clinical trials
30 with similar viruses gave us a useful insight that regulating the level of temperature
31 can provide remarkable results to arrest and stop the outbreak. Based on that
32 knowledge, some urgent solutions are proposed, which are practically without side
33 effects and very cost-effective too.

34

35 **1. Introduction:**

36

37 The recent pandemic of COronaVirus Disease 2019 (COVID-19) and its rapid
38 spread worldwide [1,2] brought the whole human civilization to a standstill. The
39 responsible virus for the disease is Severe Acute Respiratory Syndrome
40 CoronaVirus 2 (**SARS-CoV-2**) [3]. Detailed analysis of the characteristics of the virus
41 and the nature of the disease is outlined in current research [4,5].

42 The disease first originated in the Wuhan Province of China. The case of
43 hospital admission was first reported on 12th December 2019 and since then till 15th
44 March there were 80,995 reported cases in China with 3,203 confirmed deaths [2].
45 Various analyses on the COVID-19 spread in China were detailed in a recent
46 study[6]. That figure all over the globe reached 1,000,249 and 51,515 respectively [2]
47 on 3rd April 2020, since 31 December 2019. Those are 19,845,788 and 731,263
48 respectively [2] on 10th August 2020. Geographic distribution of COVID-19 cases
49 worldwide in early months of pandemic is presented in Fig.1 and cases are mainly

50 seen prevalent in the northern hemisphere. Later months, countries of Southern
51 Hemisphere were similarly affected. Because of the highly contagious in nature [3,7],
52 most of the countries worldwide started lockdown situation from around third week of
53 March [8].

54 Several facts highlighted that the spread of recent Coronavirus pandemic
55 showed some geographical preferences (Fig.1). During early days of pandemic,
56 countries and cities with moderately cold winter temperature indicated a rapid spread
57 (UK, Italy, Spain, France, northern USA etc.) compared to warm countries (e.g.,
58 countries from the African continent, Indian subcontinent and, Australia) [1,2].
59 Moreover, very cold countries like Canada, Russia and Scandinavian countries only
60 showed moderate severity. Interestingly, some countries that suggested moderate
61 severity started showing a sign of more severity from the end of April. More
62 importantly, it happened in spite of a global lockdown situation. Over the same time,
63 some warm countries (e.g, Brazil, Chilli) also suggested an increase in severity [1,2].

64 On a regional basis, compared to warmer places, colder regions were seen
65 more affected. During February and January 2020, a sub-zero minimum temperature
66 was noted in the Wuhan province of China where the outbreak was reported first.
67 Wuhan experienced maximum severity in terms of the death toll and the rapid rise of
68 infected patients. In February this year, the following cities (Rome in Italy, Tehran in
69 Iran, Seoul in South Korea) all experienced a sub-zero minimum temperature and
70 coincidentally showed a sharp increase in the number of infected patients. Those
71 cities were the epicentres of the outbreak of respective countries. The numbers of
72 infected people in Italy, Iran, South Korea are reported to be 115242, 50468 and
73 10062 (as of 3rd April 2020 since 31 December 2019) [2].

74 Close connections between epidemics and seasons are previously identified
75 for mid-latitude temperate regions; which is November till March in the Northern
76 Hemisphere, while May upto September in the Southern Hemisphere [9,10,11]. In
77 temperate regions, absolute humidity minimizes in winter alongside temperature
78 which becomes more susceptible to certain virus transmission and survival [10].

79
80 Some results of clinical trials are discussed. A laboratory study using a
81 seasonally dependent endemic virus that has close resemblance with Coronavirus
82 also confirmed the dependence of temperature and humidity on the spread of
83 disease [11]. It showed that at a temperature of 5 °C and relative humidity (RH) 35%
84 to 50% the infection rate was very high (75-100%). Whereas, when the RH was still
85 kept at 35%, but only temperature was increased to 30°C the infection rate
86 surprisingly reduced to zero [11]. As the infection rate was reduced to zero at
87 temperature 30 °C and humidity 35% that estimation may be useful for arresting
88 spread of similar viruses and needs further exploration.

89
90 Another virus named the Middle East Respiratory Syndrome Coronavirus
91 (MERS-CoV) that share genetic similarity with COVID-19 was shown to remain
92 active for a long time in low humidity and low temperature [12]. Studies with a
93 different Coronavirus SARS-CoV (Severe Acute Respiratory Syndrome Coronavirus)
94 also noted the same connection [13,14,15]. MERS-CoV and SARS-CoV both belong
95 to the Coronavirus genus in the Coronaviridae family [16].

96
97 Research also studied strength and activity for a similar generic Coronavirus
98 (viz. SARS-CoV) using a variable level of temperature and humidity [14]. It found that

99 inactivation of the virus was faster **at all humidity level** if the temperature was
100 simply raised to 20°C from 4°C. Also, the inactivation was more rapid if the
101 temperature was further increased to 40°C from 20°C, suggesting **the virus is**
102 **extremely sensitive to high temperature**. SARS could, however, be active for at
103 least five days in typical airconditioned environments which has relative humidity
104 40-50 % and room temperature 22 -25°C [13]. Studies with various Coronavirus
105 generic categories other than MERS and SARS also confirmed that low temperature
106 significantly contributes to the survival and transmission of the virus [14,17].

107

108 COVID-19 is an extremely contagious disease [3,7] as it invaded almost all
109 parts of the globe in less than two months [1,2]. The nature of its transmission under
110 variable temperature condition also needs attention. A lab experiment was
111 conducted using guinea pigs to examine the contamination of a similar seasonal air-
112 borne virus [11]. It studied the effect of temperature on airborne transmission as well
113 as contact transmission. Increasing the temperature prevented airborne transmission
114 but could not stop contact transmission. When guinea pigs were kept in separate
115 cages for 1 week at a temperature of 30°C, no infection took place among recipient
116 guinea pigs. But to simulate contact transmission, if those were kept in the same
117 cage, between 75% and 100% became infected. They, however, found **no role of**
118 **humidity in these experiments**.

119 Though the knowledge of temperature sensitivity to the similar seasonal virus
120 is recognised, whether any early warning systems can be proposed on various
121 space and time scales is yet to be determined [18]. The role of weather on similar air
122 borne viral diseases and the recent spread of COVID-19 was also studied in various
123 analyses. Research confirmed dependencies on temperature and humidity

124 [14,15,19]; wind speed and surface pressure [19] for the spread of virus. A
125 systematic review to understand the effect of temperature on COVID-19 was also
126 conducted [21] . It collected numerous recent journal submissions (around 16 in
127 number) and almost all of them indicated a strong dependence on temperature. The
128 role of global temperature on the transmission of COVID-19 worldwide was
129 mentioned first by the author in a recent work [22]. That knowledge was further
130 elaborated in a subsequent study by presenting a global temperature spatial map
131 and comparing with vulnerability worldwide [23]. There are potential that the
132 knowledge of such analyses can be used for the benefit of human society in the
133 current emergency situation. The present analysis is an extension work to
134 investigate those effects further. It also identifies countries those are more
135 advantageous/ disadvantageous stage than others in various months and seasons.
136 That knowledge has implication for future planning and setting mitigation strategy.

137 It is an extremely contagious disease [3,7] and has very high epidemic
138 potential. Scientists from different fields are working tirelessly to mitigate the crisis.
139 Popular known methods to treat disease are plasma therapy, vaccine development,
140 medication etc. But those are not yet comprehensively tested; in addition, time
141 consuming and with potential side effects. Lockdown and social distancing can be a
142 temporary solution, as the economy and mental health also need attention. With
143 those emergency situations in mind, some effective, easy solutions were also
144 proposed on 17th March 2020 [22] and further elaborated here. These are without
145 side effects, no funding is required, no vested interest involved and can be practised
146 in own home. These additional measures, apart from existing guidelines [3,7], can
147 greatly benefit to overcome the crisis.

148 This article is based on the idea whether the variable global temperature has any
149 role in the transmission of virus globally and how that knowledge can be used to
150 arrest the rapidly spreading disease.

151

152 **2. Methodology and Data:**

153 This study analysed Global Air Temperature data from NCEP/NCAR Reanalysis
154 product [24], a joint product from the National Center for Atmospheric Research
155 (NCAR) and National Centers for Environmental Prediction (NCEP). The data is
156 freely available [25]. It has a temporal coverage of Monthly as well as Daily values
157 from 1948 January till recent dates. The long-term monthly mean of this data is
158 available and derived for years 1981 - 2010. The spatial coverages extend all over
159 the globe and has 17 vertical levels. In this analysis, I only considered the lowest
160 level near the surface which is 1000mb. For air temperature, I presented the
161 climatology (30 years average), as well as some daily composites using compositing
162 technique. Results were also compared with another reanalyses product ERA5 [24a]
163 and observations are similar and hence not shown here. To find differences between
164 two sets of data, the Method of Mean Differences was applied. The level of statistical
165 significance was derived using the student's t-test. Data related to COVID-19 are
166 collected from freely available [site](#) [26].

167

168 **3. Results:**

169 **3.1 Analyses based on Temperature and spread of the Virus**

170 As temperature play a very key role in spreading Coronavirus [12,13,14,15,17] and
171 also especially COVID-19 [19, 20, 21] we analysed it further by using a spatial plot of

172 global monthly mean air temperature (Fig 2). Later it was compared with the
173 vulnerability to the disease worldwide.

174

175 **3.1.1. Mean Spatial Temperature Globally**

176 Mean global temperature spatial plot for March 2020 is shown in Fig 2a, when
177 lockdown started [8] and the disease affected most of the countries globally. Though
178 the lockdown started mainly from around third week of March in most countries, the
179 effect of lockdown on the spread of the disease was expected to be noticed around
180 April. Fig.2b is a spatial plot for the month of April 2020. Whereas, Fig. 2c covers the
181 period when the disease made its presence globally (15th Feb) till the last day of April
182 2020.

183

184 *Temperature threshold: Cold temperature*

185 Different vulnerability situation was observed for moderate cold countries and
186 extreme cold countries.

187

188 Moderate cold: The first ten countries (and number of death counts till 3rd April) in
189 descending order are mentioned: Italy (13,917), Spain (10003), United States
190 (6,053), France (4,503), China (3,326), Iran (3,160), United Kingdom (2,921),
191 Netherlands (1,339), Belgium (1011) and Germany (872) [2]. These countries
192 showing maximum vulnerability, belonged to the moderate cold category. Mean
193 temperature varied between the range of around **275°K (2°C) to 290°K (17°C)**.

194 Severe cold: Though Laboratory experiments to my knowledge did not conduct any
195 study relating to lower temperature threshold, but Fig. 1 and 2a suggested, lower
196 temperature threshold may also be important. Here are some statistics [2] for

197 reported Cases (and Deaths) for countries below 275°K (2°C), viz., Iceland 1319(4),
198 Finland 1518(19) and Canada 11268 (138); all those showed comparatively low
199 death counts till 3rd April.

200

201 *Temperature threshold: High temperature*

202 Interestingly, countries having temperature more than **300°K (27°C)** showed
203 unusually low death rate compared to the overall statistics. Countries from the South
204 Asian Association for Regional Cooperation (SAARC), South East Asian Countries
205 (SEAC), the African continent and Australia all lied in that zone and all had low death
206 counts (Fig. 1, Fig. 2a). African countries lying in that temperature zone reported
207 insignificant infected cases as well as deaths. That temperature zone excluded
208 countries with higher reported case among African continent (countries of northern
209 boundaries e.g., Algeria, Egypt and Morocco and Southern boundaries e.g., South
210 Africa). For Australia, that statistics of the reported Cases (and Deaths) were 5224
211 (23); in fact, no death was reported till 3rd of April [1] in regions when the temperature
212 is higher than 300°K (27°C). Almost all reported cases and deaths for Australia were
213 around South East part of the country where the temperature was below 300°K
214 (27°C) (Fig. 1 and Fig. 2a). Few other countries falling in that temperature threshold
215 with reported Cases (and Deaths) were Malaysia 3116 (50), Singapore 1049(5) and
216 Thailand 1875 (15) [1].

217 Certain clinical tests found the infection rate for some seasonal air borne virus
218 was **reduced to zero at temperature 30 °C at certain humidity level [11]. Here I**
219 **show that the vulnerability to COVID-19 is reduced drastically even at 27°C,**
220 without considering any effect of humidity. In addition to that, when the temperature

221 was above 305°K (32°C), an unusually low number of the reported cases, as well as
222 deaths, was observed¹.

223 These analyses indicated some rough temperature threshold for the spread
224 and vulnerability to COVID-19 as follows: i) 275°K (2°C) to 290°K (17°C) - maximum
225 reported Cases as well as Deaths; ii) <275°K (2°C)- death reporting was low; iii)
226 300°K (27°C) and above- significantly less number of reported deaths compared to
227 overall global death counts; iii) >305°K (32°C)- an unusually low number of reported
228 Cases as well as Deaths.

229 Fig. 2b is the spatial plot of global temperature for April 2020 which is tested
230 again and the main conclusion relating to temperature threshold and vulnerability
231 remain the same; and it is also true for Fig.2c.

232 The vulnerability to the disease worldwide was analysed further based on
233 certain data on the day of 1st May [26]. To examine that data till the 1st of May (Table
234 1) we compared global temperature map from 15th Feb till the end of April (Fig. 2c).
235 We find results are consistent.

236

237 **3.1.2. Examining Reported Cases and Deaths**

238 Based on location, testing facility and other various reasons reported cases are likely
239 to vary. As death reporting is usually authentic, we considered 'Deaths' as a better
240 metric. Moreover, the absolute number of deaths vary based on population. Hence to
241 analyze the degree of vulnerability, 'Deaths/Million' population of a country is chosen
242 as the best indicator in this analysis.

243 In Table 1, I have presented a few statistics showing situation update/
244 performances of various chosen countries [26]. Some countries, especially those

245 are developing could have poor reporting strategy and inadequate facilities. Tests
246 /Million population are expected to be comparatively low for those countries, as also
247 reflected in Table 1 (last column). We should note that data or statistics presented in
248 Table 1 could vary slightly and may not be accurate. However, those limitations do
249 not affect the main results of these analyses.

250 Tests /Million populations were maximum for Iceland, which was reflected in
251 the highest number of infected cases per million (column 4). Death/Infected (column
252 5) is a parameter that could indicate the performance of medical treatment country-
253 wise and expected to be lower for developed countries. However, it is also linked
254 with the number of more overaged population and number of testing etc.
255 Death/Infected (%) was highest in European countries in spite of advanced health
256 care system, that may indicate a high ageing population. The same was the lowest
257 for Singapore (.1%), which had high testing rates amongst all warm countries.

258 Data of all countries from South Asian Association for Regional Cooperation
259 (SAARC) were presented which are Afghanistan, Bangladesh, Bhutan, India,
260 Maldives, Nepal, Pakistan and Sri Lanka. All countries of South East Asian region
261 were also presented in Table 1. Those are Singapore, Cambodia, Malaysia,
262 Vietnam, Thailand, Indonesia, Philippines and Myanmar. Among those, some are
263 very popular tourist spots and some are popular international business hubs where
264 more transmission of the disease by foreign travellers are expected. In spite of the
265 varied level of testing, infrastructural facility, population density, varying degree of
266 lockdown restriction and many dissimilarities among each country there was still one
267 common factor. All those countries had very less death per million population. For
268 SAARC countries it was 2 and under; whereas, for South East Asian countries
269 (SEAC) it was 6 and under. Among these countries, Singapore did maximum testing

270 per million, which was even comparable with developed countries. That large count
271 was reflected in the higher count for infected per million compared to other countries
272 in that group, though not in the death count. Among those two groups of countries,
273 the number of deaths in one day (01/05/2020) was higher in India and Pakistan
274 compared to the rest (column 6), which was a common reflection of their high
275 population.

276

277 Following Table 1, we found the least vulnerable countries had a very less
278 count of Deaths per Million, which was under 1 (column 3). That count for less
279 vulnerable countries were 10 and under. Result of few Moderate cold countries and
280 very cold countries were also presented. For moderate cold countries, the Deaths
281 per million were very high which even exceeded 400 in some countries. Though the
282 USA ranked first in terms of total number of deaths and reported cases [1] but being
283 3rd largest populated countries in the world [27], the ranking of the USA in Table, 1,
284 column 3 was lower than European countries. For very cold countries that count was
285 less than 100 for most cases.

286

287 Following temperature thresholds upto April, we categorised countries based on
288 vulnerability as follows:

289

290 *Category I: Moderate Cold* - between 275°K (2°C) to 290°K (17°C) - Most
291 Vulnerable. Countries like USA, UK, Spain, Italy, France etc.

292 *Category II: Very Cold* – less than 275°K (2°C) - Moderate Vulnerable; e.g. Iceland,
293 Finland, Canada, Russia etc.

294 *Category III: Moderate warm – greater than 300°K (27°C) - Less Vulnerable; e.g.,*
295 SAARC, South East Asian countries, African continents, Australia.

296 *Category IV: Very warm – greater than 305°K (32°C)- Least Vulnerable. Part of*
297 African continents and Australia

298 There could still be a very few countries suggesting as outliers. Those could be
299 related to relaxed/ effective social isolation policy and preventive measures, low/high
300 testing facility, relaxed/ regulated overseas arrivals, poor/advanced infrastructure,
301 inadequate/ appropriate medical intervention on time, other favourable/ unfavourable
302 atmospheric conditions etc.

303

304 **3.1.3. Statistical Analyses**

305

306 Fig.3 showed vulnerability to COVID-19 measured in terms of Deaths per Million,
307 upto 1st of May, 2020. Fig.3a suggested all Warm countries together (SAARC and
308 South East Asian countries (SEAC), continents of Australia and Africa) had
309 significantly low death rates compared to cold countries. Mean and standard
310 deviation of moderately cold (395.8, 125.0), very cold (41.5, 34.8) and warm
311 countries (2.1, 2.4) suggested a clear distinction. In the group of warm countries,
312 there were enough dissimilarities among each other in various respect (varied testing
313 level, popular tourist destination, infrastructural facility, other atmospheric
314 conditions, developed/developing status of countries etc.). The low mean and
315 standard deviation clearly indicated how strong was the role played by temperature.
316 The method of mean difference is applied among the three categories and to test the
317 level of statistical significance, 't' test is used. The difference between each other in
318 the three categories are significant even at the 99% level. In Fig. 3b, we further

319 elaborated on warm countries and presented box plots focusing on countries from
320 SAARC and SEAC. Each group comprises of a total of 8 countries. The SAARC
321 group of countries indicated the lower mean value (1.0) and standard deviation (0.8)
322 than the group of SEAC (2.6 and 2.2, respectively). Fig. 3c further focused each
323 individual countries from Fig. 3b. Among SAARC countries, Pakistan, Afganistan
324 and Maldives showed highest rate; while from SEAC, countries with high death
325 counts were Combodia and Philipines. Fig.S1 is same as Fig. 3 though considered
326 reported Cases per Million instead of Deaths. Countries with more number of testing
327 sometimes report more cases (e.g., Singapore, Maldives and Iceland).That is one of
328 the reasons for large standard deviations in Fig S1a. Like Death, there is a very clear
329 distinction between three categories (Fig S1a). In Fig.S1b, we excluded two outlier
330 countries Singapore and Maldevis those did very high testing compared to the rest.
331 The boxplot of SAARC and SEAC do not differ much. In Fig.S1c too, we excluded
332 those two outliers for general comparison. As the reported case is heavily dependent
333 on number of testings and other factors, rankings of individual countries in Fig.S1c
334 differ to that from Fig.3. Among SAARC countries, the ranking of Pakistan was
335 highest for both, the Deaths as well as reported Cases per million.

336 Even till today (10th of August 2020), Deaths per Million for all countries from SAARC
337 and SEAC are below 34 [26]. On the otherhand, Death per Million for USA, UK,
338 Spain, Italy, France, Sweden, Belgium over the same time are all above 465 [26].
339 However, because of large population, India is now one of the highest ranked in
340 overall counts of total Deaths, as well as Cases.

341

342 **3.2. Effect of Temperature Regionally and Transition Phase:**

343 Regional temperatures within a country can vary to a large degree, (even ~ 25°C for
344 the USA, Fig. 2). Hence vulnerability of any country will also depend on regional
345 variations of temperature and discussed further.

346 **3.2.1. Regional Variation.**

347 Fig. 4a, indicated that the southern part of Canada was mostly affected compared to
348 the rest of the country. Interestingly, that region only lied in the most vulnerable
349 temperature zone (Fig. 2c). A transition was noticed from March to April and more
350 parts of southern Canada entered in moderately cold category in May indicting a rise
351 in vulnerability. The spatial plot of Canada (Fig. 4a) and temporal pattern (Fig. 4b)
352 indicated such features. The daily death count increased during the beginning of
353 April (Fig. 4b). A very high number of daily deaths were reported on the 1st of May
354 (Table 1, 6th column), which was comparable to most vulnerable countries.

355 In spite of a lockdown situation globally [8] if there was an increase in
356 Deaths/Cases to some countries that needed attention too. At the end of April, many
357 countries started moving from one vulnerability state to others, e.g., Russia, Canada
358 and some Scandinavian countries. For Russia, new cases reported on 7th May was
359 10,559, which was 2nd highest reported case after the USA[26]. Canada also
360 reported very high death on that day, which was 189, and again comparable with
361 vulnerable countries [26]. For Sweden, the death reported on 7th May was 87 which
362 was relatively high compared to the overall population of 10,089,795 [26]. These
363 countries were very cold in March, though phased out to moderate cold phase at the
364 end of April.

365 **3.2.2.The Transition of Spatial Pattern**

366 A recent research [19] studied the effect of temperature on the spread of
367 COVID-19 in Italy. It showed only 2°C rise in temperature can have a comparable
368 effect on the transmission of the virus. The effect of small change in temperature
369 even for 2°C to 2.5°C was analysed and discussed for a few continents in Fig 5
370 (Europe), Fig. S2 (Africa) and Fig. S3 (South America).

371 A spatial plot particularly focused on Europe (Fig. 5) suggested that UK was
372 still in the most vulnerable zone in April; whereas, southern Europe turned warmer
373 (Fig. 5 a and b). Scandinavian countries like Sweden started entering into most
374 vulnerability zone from moderate vulnerability state (Fig. 5 a and b). As Europe
375 turned warmer from moderately cold, death rate decreased and the same pattern is
376 observed till the beginning of August.

377 For Africa, the region of least vulnerability was marked by dark red (Fig. S2).
378 The temperature increased around latitude 10°N -15°N in April and Table 1 (6th
379 column) showed no new death was reported to those countries. Questions could be
380 raised about poor testing and reporting in those African countries. One reason could
381 be as death was reported zero, those underdeveloped countries may not have
382 considered testing a priority. Moreover, in Australian continents without much of an
383 issue of testing and reporting also suggested similarly. In fact, part of western
384 Australia and northern territory (least vulnerable region, Fig.2) did not have deaths
385 and practically few reported cases [1] (hence not shown in Table 1). A shift in high
386 temperature region in Africa from south to north during March to April gave an
387 indication of how the vulnerability can shift regionally and gave rough time
388 estimations of that transition. Northern territory of the continent turned warmer in
389 April from March, while southern territory (that include south Africa) started to
390 become cooler (Fig S2).

391 As 2°C change of temperature can influence the transmission of the disease
392 [19], I wanted to explore that for South America (Fig. S3) too. Some countries from
393 South America suddenly started an increase in deaths and reported cases. On 7th
394 May, Brazil reported new daily death 667, the 2nd highest after USA [26]. The
395 lowering of temperature in Southern Brazil (297°C to 291°C in April) is clearly distinct
396 in Fig. S3b to that from Fig. S3a.

397 **3.2.3. Temporal Pattern.**

398 Fig. 6 showed daily confirmed COVID-19 Deaths per Million in a form of
399 rolling 7-day average upto 6th May. Those statistics were consistent with the number
400 of total Death counts per Million (Table 1, 3rd column). There were clear distinctions
401 throughout the time period among moderately cold, very cold and warm countries. All
402 warm continents e.g., Asia, Africa and Australia, those belonged to the less
403 vulnerable category, suggested a very nominal daily death count rate compared to
404 the rest (not visible as merges with X axis). The bottom three curves are for Russia,
405 Brazil and Canada respectively. All three were showing a rising trend and we
406 discussed earlier those three were in the transition state. Russia and Canada were
407 turning from very cold to moderate cold; whereas, Brazil from warm to cold and all
408 cases Death rate was increasing. For the USA, UK, Italy and Spain all suggested
409 very high count throughout and all already achieved a peak and were shown in the
410 declining state.

411 In terms of population, three highly populated countries are considered here
412 viz., the USA, Brazil and India (world ranking 3rd , 6th and 2nd respectively) [27]. A
413 plot of daily death upto 2nd May was presented for those three countries (Fig. 7a).
414 The USA, a vulnerable country showed a very high daily count, Brazil in a transition
415 phase from warm to cooler state, suggested high death count with a comparatively

416 steeper rise in later periods. India the less vulnerable country was moving from warm
417 to warmer. It reported much less death count compared to the rest two.

418 Temporal pattern of these three countries is also consulted upto recent period
419 in Fig 7b. They ranked 1st, 2nd and 3rd respectively globally in terms of total Cases
420 and daily Deaths on 11th August 2020 [26]. The USA peaked around April and after a
421 decline it again started showing a rise in recent period. Brazil reached a peak at
422 around June and still continued with that trend without a decline. Whereas, India is
423 showing a steady rise and did not reach a peak yet. The 7-day average shows the
424 maximum count for India is the lowest till date; USA the highest, followed by Brazil.
425 The steady rising trend of India and its consequence indeed deserve attention.

426 Based on the discussion, it is possible to determine whether the risk from the
427 virus of a specific country as a whole and region-wise is increased or decreased
428 during different time periods.

429

430 **3.3. Future Predictive Maps based on Temperature:**

431 Climatology of temperature is prepared globally for different months (Fig. 8,
432 Fig. S4-S8). Following the current analyses, it would indicate predictive maps of
433 vulnerability for different months based only on temperature. Figure 8 (a, b) are for
434 July and August respectively, while Fig. S4-S8 for rest other months. Those show
435 Fig 2a is consistent with Fig S5 (top) and Fig. 2b with Fig S5 (bottom), which are for
436 the month of March and April respectively. As we verified it for last March and April
437 (2020) with the climatology of those two months, we may expect the predictive maps
438 would be very similar for other months too.

439 Future predictive maps can indicate, which countries are in advantageous/
440 disadvantageous state in the coming months based only on temperature
441 variation. It indicated that during July, South America, Australia and South Africa will
442 turn colder (compare between Fig. 2 and Fig. 8a) and need additional risk-based
443 preparedness. Iceland, Russia will turn moderate cold from very cold. Europe will
444 turn warmer and will reduce risks. Following this future predictive map, the death rate
445 in Europe indeed reduced this July; while South America, Australia, South Africa
446 showed a rise. Iceland and Russia also reported increase in cases as well as deaths.

447 Such future predictive maps can give ideas of associated risks to different
448 countries month-wise and the direction of transitions. It will be important for every
449 country for future preparedness and planning.

450 **3.4. Additional Points need Attention**

451 Few additional points need attention for preparing future strategy.

452 *i) More use of Air Conditioning (AC) in very warm countries:* In June, July some
453 countries reached more than 310°K (37°C) temperature (Fig. 8a; Fig. S6,bottom). In
454 that uncomfortable range of temperature, rich to middle-income group of people and
455 economically affluent countries are likely to use more AC. That might cause more
456 spread of the disease within the same household, especially in highly populated
457 countries. Similar category Coronavirus was found active for at least five days in
458 typical airconditioned environments [13]. That could be one possible reason for
459 recent surge in Cases and Deaths in very warm (>310°K) countries e.g., countries
460 like Iran, Iraq etc. in July-August.

461 Air circulation for half an hour daily and regular disinfecting AC premise could be
462 useful to arrest spreads.

463 *ii) Mass Gathering:* Mass gathering in any city or places later showed a surge in
464 infections and deaths after certain days of lag. Scafetta also discussed that issue for
465 various places, including Carnival in Louisiana state, USA [19]. Recently, *Black Lives*
466 *Matter protests* took place in many parts of the USA. Many did not follow
467 precautionary measures and distancing rule, which may have certain bearings in the
468 surge in Cases and Deaths in the USA since beginning of July (Fig. 7b). Any mass
469 gathering needs further attention/ analyses to prevent future outbreaks.

470 *iii) Outliers Countries and states:* There could be very few countries standing as
471 outliers. Examples of outlier countries from South America are Uruguay
472 and Paraguay. They reported unusually low deaths compared to neighbouring
473 countries [26].

474 An example of outlier state is Kerala from India. The first case of COVID-19 in
475 India was spotted in Kerala. In spite of high population density, they could manage
476 the number of deaths remarkably low compared to all the neighbouring states. That
477 trend is maintained throughout the period till date. All neighbouring states have very
478 similar weather conditions. Kerala set an example to the country as well as at
479 international level. On the contrary, only one state Maharashtra in India is accounting
480 for roughly 40% of the total deaths of the country [33a].

481 Those suggest country level and state level effective intervention can play a
482 vital role. Outlier countries and cities need more attention to gaining insight for future
483 global action.

484 *iv) Case example of a Country (South Africa from African Continents) and State*
485 *(Victoria in Australia):* Among land-locked countries from African Continents, South
486 Africa reported maximum Deaths as well as Cases. South Africa (at the southern
487 part of the continent) is comparatively cooler than almost all other African countries.
488 In June and July, it was coldest among all the African countries (see Fig. S6 and
489 Fig. 8a, even reached less than 290 °K) and simultaneously increased daily death
490 counts. Interestingly, South Africa has the highest total testing than other countries of
491 the continent. Deaths per Million in South Africa is highest among all countries from
492 the continents and it is 181 till 11th August 2020 [26]. The same count for most of the
493 countries of African continent is below 20.

494 Similarly, the state Victoria in Australia noted a Surge in Cases as well as Deaths in
495 recent period. After a peak at around April 2020, Australia reported practically zero
496 daily death during whole of June. It suddenly showed a 2nd surge and daily Death
497 count (absolute count, 3-day rolling average, as well as 7-day rolling average)
498 reached highest on the day of reporting (11th August) [26]. Situated in the south-east
499 part of Australia, Victoria was the coldest part of the country in July (temperature
500 even less than 285°K, Fig 8a) and interestingly showed maximum surge in cases
501 and deaths in recent days compared to other states.

502 Such observation strengthened the fact that the role of temperature cannot be over-
503 ruled on the spread and vulnerability of the disease, regionally as well as globally.

504 *v) Major Cities:* This is an extremely contagious disease and single contamination
505 through a foreign carrier/traveller can multiply exponentially among locals.
506 Megapolises like New York, Mumbai, London were expected to be infected more

507 than its suburb and it was, in fact, the case. All these factors need to be taken into
508 account in doing any statistical analyses. This analysis is free from such biases.

509 *vi) Risk less in Summer than winter?* Risk of a person from the disease also depend
510 on how much virus entered in the body. In summer, if anyone is in the cold Air-
511 Conditioned (AC) room the whole day with a COVID-19 infected person, it could be
512 riskier than anyone in winter who are outside in open air with a COVID-19 patient for
513 a short time. It explains why many young doctors and nurses without morbidity
514 conditions died. Many police and security service personal also died though they
515 were sound in health. Again, if people are outside in summer with a COVID-19
516 infected person, the risk is less compared to winter. Studies suggested that air
517 borne seasonal viral transmission is reduced in high temperature environment [11] .
518 All these analyses are useful to set proper mitigation strategy to tackle the crisis.

519 **3.5. Possible Solutions:**

520 The above analyses highlighted that temperature plays an important role in
521 transmissions of Coronavirus [12,13,14,15,17] that include COVID-19 [19,20,21].
522 Warm temperature drastically reduces its impact. Hence following urgent measures
523 (also mentioned earlier [22, 23, 23a,23b]) are proposed to arrest and stop the
524 outbreak:

- 525 • *Sauna facility:* Usually hotels, gyms, leisure centres have existing Sauna
526 facilities. Also, mobile and Caravan Sauna facilities can be thought of in
527 future.
- 528 • *Portable Room Heater:* Stay close to a portable room heater twice a day
529 around half an hour. Being portable in nature, it can be moved around and

530 many people can avail that facility in a flexible way. Room heaters can also be
531 useful for disinfecting purposes.

532 • *Regulate room temperature of Air Conditioning (AC):* Maintain room
533 temperature of AC a bit higher than usual. Maintaining comfort level, a high
534 temperature threshold can be regulated inside offices, schools, colleges,
535 shopping malls etc. Attention should be more on sensitive places like old care
536 homes, health centres, and hospitals (other than special treatment units
537 where cold temperature is essential or recommended).

538 • *Disinfect any place using High Temperature:* Before start of office, school or
539 business, temperature of premises may be kept very high, (say, 60°C) for half
540 an hour. For airports, train and bus, same method of disinfecting could be
541 thought of. *Optimum temperature and duration can be tested easily.* For any
542 external object or material, disinfecting using very high temperature could be
543 a useful solution.

544 • *Using Blow dryers (Hair dryer) :* Inhale hot air through nose few times a day to
545 kill virus in nasal cavity.

546 • *Hot Drinks:* Hot drinks (could be tea, coffee, warm milk, hot water with
547 lemon, etc.), gargle with warm salt water few times a day to destroy virus in
548 throat.

549 The last two measures are proposed because the virus, which is very sensitive to
550 Temperature, mainly enters through the nose (WHO) [3]. Testing is done with
551 swab from nasal cavity and back of the mouth. High temperature will reduce the
552 number in nose and throat where the virus largely accumulates. Thus, body will have

553 strength and time to defend the disease easily. These measures described above
554 could be very effective when people are in the asymptomatic, pre-symptomatic state
555 or initial stage of disease. An overview depicting actions towards Solutions in a form
556 of schematic is presented in Fig.9.

557 The main point in this analysis is that the virus is very sensitive to temperature.
558 Based on that knowledge these few measures are proposed. All solutions, as
559 supported by science, can further be strengthened by clinical trials, side by side.
560 Many simple, easy procedures serving the purpose can be thought of; some could
561 be applicable to warm countries and some to cold countries. Few options for people
562 of lower income groups and for rural and remote locations are mentioned.

- 563 • *Green House (glass)*: It would be useful in poor countries and rural places
564 without electricity. During the day, bright sunshine can provide heat by Green
565 House effect.
- 566 • *Outside Raw Fire*: In underdeveloped countries and rural places, people
567 usually circle round in a camp-fire style fire in winter. They use dry leaves and
568 spare woods for a small fire. That heat in winter could be useful.
- 569 • *Substitute of Blow Dryer (Hair Dryer) and Room Heater*: While cooking, all
570 members of the household could be, in turn, stay close to the heat source, for,
571 say, half an hour a day. Also, each individual can use separate folded cotton
572 cloths to take heat from the cooking container and use on the nose.

573 Study showed SARS-CoV-2 is more infectious than some other Coronaviruses [34].
574 The usual incubation period for COVID-19 is around 14 days [7]. The virus can stay
575 in the human body for a few days without showing symptoms though still could be a

576 carrier [3,7]. As it is difficult to trace mild or pre-symptomatic infection, it has greater
577 epidemic potential [34]. Given the emergency situation, lots treatment/ medicines
578 are desperately tried which are fraught with risks of serious side effects. On the
579 contrary, this solution has practically zero side effects. This study suggests the
580 majority of world populations need to be well prepared before the coming winter.
581 This is an extremely contagious disease [3,7]. Social isolation and lockdown can be
582 a temporary solution, as the economy and mental health also need attention.

583 These measures, as mentioned, are likely to reduce the spread dramatically. If few
584 of these measures are implemented worldwide, it will have a major impact to arrest
585 the spread of the virus.

586 **Caution and Additional Points**

587 *Caution:* If people already developed major symptoms, then all these methods
588 discussed will not be effective and proper medical advice need to be solicited.

589 *Additional Points:*

- 590 • *Water shortage:* Whether frequent Hand Washing can be replaced by heat
591 sensor-based hand dryer (normally found in a washroom).
- 592 • *Plastic Disposal:* Personal Protective Equipment (PPE) are single use. World
593 is already under stress due to problems of disposing Plastic. If PPE can be
594 disinfected using heat-based solutions and reused. It can be tested in
595 laboratory and could prove very beneficial.

- 596 • *Face Shield/ Visor:* In busy public places, mass gathering, and cold premise,
597 face shield will give additional protection. The virus can also enter through
598 eyes (ECDC).
- 599 • *Contact Transmission:* For warm, highly populated countries, contact
600 transmission could play important role and appropriate measures can be
601 taken. E.g., Air Conditioned (AC) premises, where mass gathering happens
602 need disinfecting on a regular basis.
- 603 • *Air Circulation:* In all AC room, fresh air circulation for half an hour a day is
604 advisable. For warm countries, that timing around noon to early
605 afternoon, when daily temperature is highest, could be more beneficial.

606

607 **4. Conclusions:**

608 This article investigated the influence of temperature globally in the spread
609 and vulnerability to COVID-19. It showed the temperature was a crucial factor in
610 transmitting the virus. The most favourable state for the spread of the virus was
611 moderately cool places and countries; whereas warm countries were likely to be less
612 affected. Temperature dependencies were also noticed in clinical trials
613 those involved similar category Coronavirus (MARS, SARS etc.) and seasonal
614 influenza/flu virus.

615 For analysing vulnerability, Deaths per Million population was considered as a
616 useful and effective metric. Four different categories of vulnerability were identified
617 based on temperature variations - which are moderately cold, very cold, moderately
618 warm and very warm. Focusing on Temperature Range (upto April), the max

619 reported Cases, as well as Deaths, were noted when the temperature was
620 *moderately cold*, which was between the threshold of around 275°K (2°C) to 290°K
621 (17°C). Based on temperatures of March and April, the USA, UK, Italy, Spain,
622 France etc. belonged to this category. The vulnerability was moderate for *very cold*
623 countries, i.e., when the temperature was less than 275°K (2°C) and countries in that
624 category for March and April were Russia, Canada, Iceland and Scandinavian
625 countries. A significantly lesser degree of vulnerability was noted for *warm* countries
626 with temperatures 300°K (27°C) and above. SAARC countries, South East Asian
627 countries (SEAC), African continents and Australia belonged to that category in
628 March and April. In fact, when the temperature was *very warm*, more than 305°K
629 (32°C) [maximum temperature upto April was around 310°K], there were an
630 unusually very low number of reported cases as well as deaths. Some parts of
631 Australia and African continents showed such behaviour in March, April.

632 Statistical analyses suggested the vulnerability to the disease was significantly
633 different, between each other, for moderately cold, severe cold and warm countries.
634 For warm countries, further analyses on the group of all SAARCs and SEAC were
635 conducted and individual countries were also compared. The low mean and standard
636 deviation for Deaths/ Millions of all SAARC and SEAC countries indicated again the
637 strong role of temperature.

638 This analysis can also give some idea for regional variation of vulnerability of
639 various countries and it specifically discussed that for Canada. Spatial variations
640 within continents were discussed for Europe, South America and Africa for the month
641 of March and April. Based on temperature variations, countries can move from one
642 vulnerability state to the other. For e.g., parts of Russia, Canada started

643 entering severe cold to moderate cold state at the end of April; whereas, Brazil and
644 few warm countries from South America moved from warm to a less warm state. In
645 spite of the lockdown situation worldwide at that time, those countries reported a
646 sudden rise of death and infected cases at the beginning of May. Europe turned
647 warmer from moderately cold and death rate decreased in later periods.

648 The rolling 7-day average of daily confirmed COVID-19 Deaths per Million over
649 the period (till the beginning of May) is also discussed. It was consistent with the total
650 number of Deaths/Million. There were clear distinctions throughout the time period
651 among moderately cold, very cold and warm countries. All warm continents e.g.,
652 Asia, Africa and Australia, those belonged to a less vulnerable category, suggested a
653 nominal daily death count rate compared to the rest. The USA and European
654 countries showed a decline at later periods, while Russia, Canada and
655 Brazil showed a rise.

656 Three highly populous countries USA, Brazil and India were focused those
657 ranked 1st, 2nd and 3rd respectively globally in terms of total Cases and daily Deaths
658 till today (on 11th August 2020). In terms of daily Deaths, the USA peaked around
659 April and after a decline, it again started showing a rise in the recent period. Brazil
660 reached a peak at around June and still continued with that trend without a decline.
661 Whereas, India is showing a steady rise and did not reach a peak yet. The steady
662 rising trend of India and its consequence indeed deserve attention.

663 This analysis presented future predictive maps month-wise based only on
664 temperature variation. That could indicate, which countries are in advantageous/
665 disadvantageous stage in the coming months. It predicted that the situation will
666 worsen in July for South America, Australia, Iceland and South Africa, while will

667 improve for Europe and that indeed happened. Current analyses and predictive
668 maps have major implications for future planning and preparedness. This study also
669 discussed issues which are useful to set proper mitigation strategy to tackle the
670 crisis.

671 Like other similar category viruses, this virus is also very sensitive to
672 temperature. It gave a valuable insight that regulating temperature level can provide
673 a useful strategy to arrest and stop the outbreak. Some urgent solutions are
674 proposed based on that knowledge. It is very cost-effective and practically without
675 side effects. These measures are likely to reduce the spread of the disease
676 dramatically.

677

798 **List of Table**

799 Table 1: Reported Cases, Deaths and Tests of few Countries as of 1/5/2020

800

801 **List of Figures**

802 **Fig. 1.** Geographic distribution of COVID-19 reported cases worldwide, as of 16th

803 March 2020 [1].

804 **Fig. 2.** Monthly average air temperature (^oK) spatial plot **Globally** for: a) March

805 2020; b) April and c) Feb 15 till April 2020. Plots are generated from the

806 NOAA/ESRL Physical Sciences Division, Boulder Colorado web site at

807 <https://psl.noaa.gov/data/composites/day/>

808 **Fig.3.** Vulnerability to COVID-19 measured in terms of Deaths per Million, upto 1st of

809 May 2020. a) Deaths in Moderately cold, Very cold and Warm countries are shown.

810 In category 3, all Warm countries (SAARC and South East Asian countries (SEAC),

811 continents of Australia and Africa) together are presented. Uncertainty at one

812 standard deviation level is marked. b) Box plot with particular focus on SAARC and

813 SEAC groups. c) Record of each individual country from b.

814 **Fig. 4.** Spatial and Temporal distribution of COVID-19 deaths in Canada till 2/5/20.

815 a) Regional distribution of reported death [28]. b) The actual number of deaths

816 reported in each day suggests a rising pattern [29].

817 **Fig. 5.** Mean Air temperature in March (Top) and April (Bottom) for Europe in

818 NCEP/NCAR Reanalyses.

819 **Fig. 6.** Rolling 7-day average of daily confirmed COVID-19 deaths per million upto
820 6th May 2020 [33]. India, Asia, Africa and Australia all are very low compared to the
821 rest throughout and practically merges with X-axis (hence not visible). The bottom
822 three curves are for Russia, Brazil and Canada respectively. All three are showing a
823 rising trend. Top four high peak curves are for UK, USA, Spain and Italy. All four are
824 currently in a declining state. Plot generated using: [https://ourworldindata.org/
825 grapher/ daily-covid-deaths-per-million-7-day-average](https://ourworldindata.org/grapher/daily-covid-deaths-per-million-7-day-average), accessed on 10/05/2020.

826

827 **Fig. 7.** Daily death counts of three very high populated countries e.g., USA, Brazil
828 and India; a) upto 2nd May 2020, b) upto 11th August 2020. a) The USA showed very
829 high range (maximum 2624), Brazil moderate (maximum 474) and India low
830 (maximum 77). Note three different ranges of Y axis of three countries, USA[30],
831 Brazil [31] and India[32]. b) Apart from Daily Deaths, 3 day moving average and 7
832 day moving average is also marked by different colours. Peaks and troughs, which
833 arise in 3-day average plot mainly due to weekend (less) reporting issues is
834 eliminated in 7-day average plot. Moreover, 7-day average plot also smoothed out
835 sudden spikes which usually arises due to rectification of past reporting (as seen for
836 India). The 7-day average shows the maximum count for India [32a] is the lowest till
837 date; USA [30a] the highest, followed by Brazil [31a].

838 **Fig. 8.** Climatology of global temperature for July (a) and August (b).

839 **Fig. 9.** An overview depicting actions towards Solutions at Individual level (right) and
840 General or Public level (left) in a form of schematic.

841

842

843 **Supplementary Section**

844 **List of Figures**

845 **Fig. S1.** Same as Fig.9 (a,b,c) respectively, but instead of 'Death', it presented
846 'Cases' per Million. In c) Maldives and Singapore are shown as outliers (upper bound
847 skipped) and those two are omitted in b).

848

849 **Fig. S2.** Mean Air temperature in March (Top) and April (Bottom) for Africa in
850 NCEP/NCAR Reanalyses

851

852 **Fig. S3.** Mean Air temperature in March (Top) and April (Bottom) for South America
853 in NCEP/NCAR Reanalyses.

854

855 **Fig. S4.** Climatology of global temperature for January (top) and February (bottom).

856

857 **Fig. S5.** Climatology of global temperature for March (top) and April (bottom).

858

859 **Fig. S6.** Climatology of global temperature for May (top) and June (bottom).

860

861 **Fig. S7.** Climatology of global temperature for September (top) and October
862 (bottom).

863

864 **Fig. S8.** Climatology of global temperature for November (top) and December (bottom).
